The GBG Class Interface Tutorial V2.1: General Board Game Playing and Learning

Wolfgang Konen

Computer Science Institute,
TH Köln,
Cologne University of Applied Sciences,
Germany

wolfgang.konen@th-koeln.de

Last update: May 2020

Abstract

This technical report introduces GBG, the general board game playing and learning framework. It is a tutorial that describes the set of interfaces, abstract and non-abstract classes which help to standardize and implement those parts of board game playing and learning that otherwise would be tedious and repetitive parts in coding. GBG is suitable for arbitrary 1-player, 2-player and N -player board games. It provides a set of agents (AI's) which can be applied to any such game. This document describes the main classes and design principles in GBG.

This document is an updated version of the 2019 GBG tutorial¹ (new sections on *BoardVector*, *GBGLaunch*, *GBGBatch* and *Design Principles*).

GBG is written in Java and available from GitHub.²

1 Introduction

1.1 Motivation

General board game (GBG) playing and learning is a fascinating area in the intersection of machine learning, artificial intelligence and game playing. It is about how computers can learn to play games not by being programmed but by gathering experience and learning by themselves (self-play). The learning algorithms are often called AI agents or just „AI“s (AI = artificial intelligence). There is a great variety of learning algorithms around, e.g. reinforcement learning algorithms like $TD(\lambda)$, Monte Carlo tree search (MCTS), different neural network algorithms, Minimax, ... to name only a few.

Even if we restrict ourselves to board games, as we do in this paper (and do not consider other games like video games), there is a plethora of possible board games where an agent might be active in. The term „General“ in GBG refers to the fact that we want to have in the end agents or AIs which perform well on a large variety of games. There are quite different games: 1-person games (like Solitaire, 2048, ...), 2-person games (like TicTacToe, Othello, Chess, ...), many-person games (like Settlers of Catan, Poker, ...). The game environment may be deterministic or it may contain some elements of chance (like rolling the dices, ...).

A common problem in GBG is the fact, that each time a new game is tackled, the AI developer has to undergo the frustrating and tedious procedure to write adaptations of this game for all agent algorithms. Often he/she has to reprogram many aspects of the agent logic, only because the game logic is slightly different to previous games. Or a new algorithm or AI is invented and in order to use this AI in different games, the developer has to program instantiations of this AI for each game.

Wouldn't it be nice if we had a framework consisting of classes and interfaces which abstracts the common processes in GBG playing and learning? If someone programs a new game, he/she has just to follow certain interfaces described in the GBG framework, and then can easily use and test on that game *all* AIs in the GBG library.

Likewise, if an AI developer introduces a new learning algorithm which can learn to play games, she has only to follow the interface for agents laid down in the GBG framework. Then she can test this new agent on *all* games of GBG. Once the interface is implemented she can directly train her agent, inspect its move decisions in each game, test it against other agents, run competitions, enter game leagues, log games and so on.

The rest of this document introduces the class concept of GBG. After a short (and probably incomprehensive) summary of related work in Sec. 1.2, Sec. 2 gives an overview of the relevant classes and Sec. 3 discusses them in detail. Sec. 5 discusses some use cases and FAQs for the GBG class framework. Appendix A gives more details on game value functions, Appendix B introduces n-tuples, and Appendix C describes the tasks in GBG which are multi-core parallelized.

See [Konen \[2019\]](#) for a more research-oriented description of GBG.

1.2 Related Work

One of the first general game-playing systems was Pell's METAGAMER [Pell, 1996]. It played a wide variety of simplified chess-like games.

Later, the discipline **General Game Playing (GGP)** [Genesereth and Thielscher, 2014, Mańdziuk and Świechowski, 2012] became a wider coverage and it has now a long tradition in artificial intelligence: Since 2005, an annual GGP competition organized by the Stanford Logic Group [Genesereth et al., 2005] is held at the AAAI conferences. Given the game rules written in the so-called *Game Description Language (GDL)* [Love et al. [2008]], several AIs enter one or several competitions. As an example for GGP-related research, Mańdziuk and Świechowski [2012] propose a universal method for constructing a heuristic evaluation function for any game playable in GGP. With the extension *GDL-II* [Thielscher, 2010], where *II* stands for „Incomplete Information“, GGP is able to play games with incomplete information or nondeterministic elements as well.

GGP solves a tougher task than GBG: The GGP agents learn and act on previously unknown games, given just the abstract set of rules of the game. This is a fascinating endeavour in logic reasoning, where all information about the game (game tactics, **game symmetries** and so on) is distilled from the set of rules at *run time*. But, as Świechowski et al. [2015] have pointed out, arising from this tougher task, there are currently a number of limitations or challenges in GGP which are hard to overcome within the GGP-framework:

- Simulations of games written in GDL are slow. This is because math expressions, basic arithmetic and loops are not part of the language.
- Games formulated in GDL have suboptimal performance as a price to pay for its universality: This is because „it is almost impossible, in a general case, to detect what the game is about and which are its crucial, underpinning concepts.“ [Świechowski et al., 2015]
- The use of Computational Intelligence (CI), most notably neural networks, deep learning and TD (temporal difference) learning, have not yet had much success in GGP. As Świechowski et al. [2015] writes: „CI-based learning methods are often too slow even with specialized game engines. The lack of game-related features present in GDL also hampers application of many CI methods.“ Michulke and Thielscher [2009], Michulke [2011] presented first results on translating GDL rules to neural networks and TD learning: Besides some successes they faced problems like overfitting, combinatorial explosion of input features and slowness of learning.

GBG aims at offering an alternative with respect to these limitations, as will be further exemplified in Sec. 1.3. It has not the same universality as GGP, but agents from the CI-universum (TD, SARSA, deep learning, ...) can train and act fast on all available games.

Other works with relations to GBG: *General Video Game Playing* (GVGP, Levine et al. [2013]) is a related field which tackles video games instead of board games. Likewise, μ RTS [Ontanón and Buro, 2015, Barriga et al., 2017] is an educational framework for AI agent testing and competition in real-time strategy (RTS) games. *OpenAI Gym* [Brockman

et al., 2016] is a toolkit for reinforcement learning research which has also a board game environment supporting a (small) set of games.

1.3 Introducing GBG

We define a **board game** as a game being played with a known number of players, $N = 1, 2, 3, \dots$, usually on a game board or on a table. The game proceeds through actions (moves) of each player in turn. This differentiates board games from video or RTS games where usually each player can take an action at any point in time. Note that our definition of board games includes (trick-taking) card games (like Poker, Skat, ...) as well. Board games for GBG may be deterministic or nondeterministic.

What differentiates GBG from GGP? – GBG has not the same universality than GGP in the sense that GBG does not allow to present new, previously unknown games at *run time*. However, virtually any board game can be added to GBG at *compile time*. GBG then aims at overcoming the limitations of GGP as described in Sec. 1.2 [Konen, 2019]:

- GBG allows fast game simulation due to the compiled game engine (10.000-90.000 moves per second for TD-agents on a single core).
- The game or AI implementer has the freedom to define game-related features or **symmetries** (for the n-tuple agents, see Sec. 3.6 and Appendix B.3) at compile time which she believes to be useful for her game. Symmetries can greatly speed up game learning.
- GBG offers various CI agents, e.g. TD- and SARSA-agents and – for the first time – a **generic** implementation of TD-n-tuple-agents (see Sec. 3.3), which can be trained fast and can take advantage of game-related features. With *generic* we mean that the n-tuples are defined for arbitrary game boards (hexagonal, rectangular or other) and that the same agent can be applied to 1-, 2-, ..., N -player games.
- For evaluating the agent's strength in a certain game it is possible to include game-specific agents which are strong or perfect player for that game.³ Then the *generic* agents (e. g. MCTS or TD) can be tested against such specific agents in order to see how near or far from strong/perfect play the generic agents are on that game.⁴ It is important to emphasize that the generic agents do *not* have access to the specific agents during game reasoning or game learning, so they cannot extract game-specific knowledge from the other strong/perfect agents.
- Each game has a game-specific visualization and an inspect mode which allows to inspect in detail how the agent responds to certain game situations. This allows to get deeper insights where a certain agent performs well or where it has still remarkable deficiencies and what the likely reason is.

³Examples are the perfect-playing AlphaBetaAgent for Connect-4 and BoutonAgent for Nim.

⁴Note that in GGP agents are compared with other agents from the GGP league. A comparison with strong/perfect game-specific (non-GGP) agents is usually not possible.

Figure 1: Class diagrams GBG: a. **StateObservation** and b. **PlayAgent**.

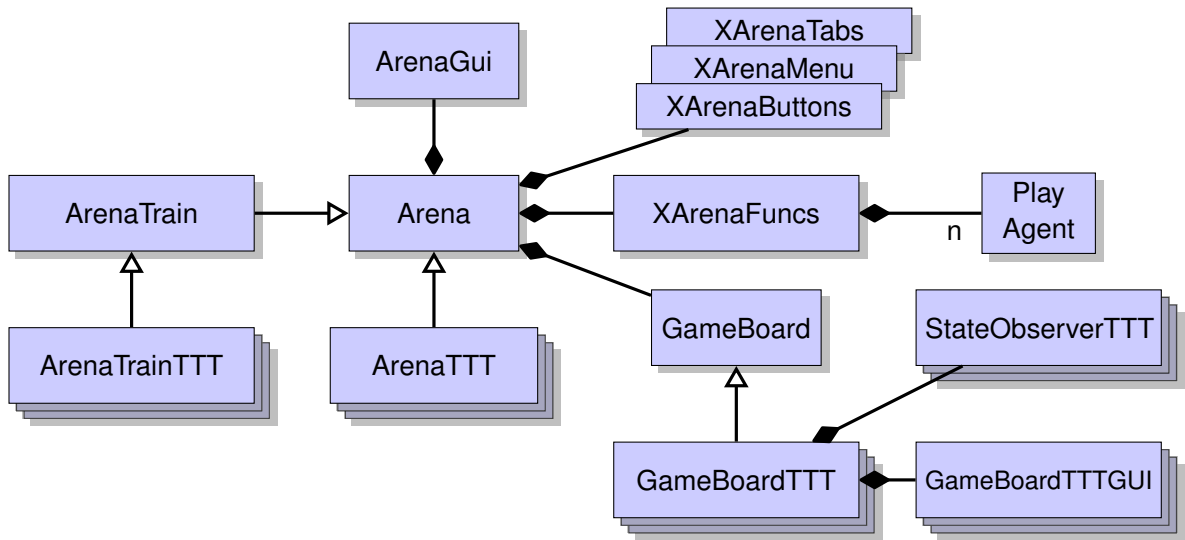

Figure 2: Class diagram GBG: Classes around **Arena**.

GBG is written in Java and supports parallelization of multiple cores for time-consuming tasks. It is available as open source from GitHub⁵ and as such – similar to GGP – well-suited for educational and research purposes [Konen, 2019].

2 Overview

2.1 Classes and Interfaces

Figs. 1 and 2 give a first overview of the classes in GBG. In these UML-like diagrams, an interface is depicted as blue half circle, an open-triangle arrow connects a child class with a parent class, and a diamond-shaped arrow connects a member with its containing class.

⁵<https://github.com/WolfgangKonen/GBG>

Interface **StateObservation** is the main interface a game developer has to implement once he/she wants to introduce a new game (Fig. 1a). A class derived from **ObserverBase** and implementing **StateObservation** observes a game state, it can infer from it the available actions, knows when the game is over, can advance a state into a new legal state given one of the available actions. If a random ingredient from the game environment is necessary for the next action (of the next player), the advance function will add it.

The second interface a game developer has to implement is the interface **GameBoard**, which realizes the board GUI and the interaction with the board. If one or more humans play in the game, they enter their moves via **GameBoard**.

The interface an AI developer has to implement is the interface **PlayAgent** (Fig. 1b). It represents an „AI“ or agent capable of playing games. If necessary, it can be trained by self-play. Once trained, it has methods for deciding about the best next action to take in a game state **StateObservation** and getting the agent's estimate of the score or value of a certain game state.

The heart of GBG are the abstract classes **Arena** and **ArenaTrain** (Fig. 2). In the **Arena** all agents meet: They can be loaded from disk, they play a certain game, there can be competitions. In **ArenaTrain**, which is a class derived from **Arena**, there are additional options to parametrize, train, inspect, evaluate and save agents. The classes **XArenaMenu**, **XArenaTabs**, **XArenaButtons** and **XArenaFuncs** are helper classes to implement the functionality of **Arena** and **ArenaTrain**.

The new Java application classes **GBGLaunch** and **GBGBatch** allow to start all game arenas derived from **Arena** and **ArenaTrain**, either with GUI or as batch w/o GUI.

The helper classes **Feature**, **XNTupleFuncs**, **Evaluator** and **ACTIONS** (+ **ACTIONS_VT**, **ACTIONS_ST**) support the abstraction in GBG.

3 Classes in Detail

3.1 Interface **StateObservation** and abstract class **ObserverBase**

Interface **StateObservation** observes the current state of the game, it has utility functions for

- returning the available actions (`getAvailableActions()`),
- advancing the state of the game with a specific action (`advance()`),
- copying the current state,
- getting the player who has to move i the current state (`getPlayer()`),
- getting the score of the current state
(`getGameScore(StateObservation referingState)`),
- signaling end and winner of the game

Example classes implementing **StateObservation** are: **StateObserverTTT**, **StateObserver2048**, ..., **ObserverBase**.

Many methods of **StateObservation** e.g. setters, getters and other common methods, have their defaults implemented in abstract class **ObserverBase**. It is strongly recommended to derive a new **StateObservation** class from class **ObserverBase**, i. e.

```
class StateObsXYZ extends ObserverBase implements StateObservation
```

If a game has random elements (like rolling the dices in a dice game or placing a new tile in 2048), `advance()` is additionally responsible for invoking such random actions and reporting the results back in the new state. Examples:

- For a dice-rolling game: the game state is the board & the dice number.
- For 2048: the game state is just the board (with the random tile added).

Interface **StateObsNondeterministic** is derived from **StateObservation** and provides functionality around nondeterministic actions. It splits the usual `advance()` in two parts: `advanceDeterministic()` and `advanceNondeterministic()`. The possible random actions in the non-deterministic part are accessible via `getAvailableRandoms()`. Examples using or implementing **StateObsNondeterministic** are **ExpectimaxNAgent** and **StateObserver2048**.

3.2 Classes **StateObsWithBoardVector** and **BoardVector**

Class **StateObsWithBoardVector** is a container class containing a **BoardVector** object and its creating **StateObservation** object.

Class **BoardVector** contains an `int[]` representation of a **StateObservation** object. See Appendix B.1 for a specific example and Sec. 5.8 for several **BoardVector**-creating methods.

3.3 Interface **PlayAgent** and abstract class **AgentBase**

Interface **PlayAgent** has all the functionality that an AI (= game playing agent) needs. The most important methods are:

- `getNextAction2(sob, ...)`: given the current game state `sob`, return the best next action.
- `double getScore(sob)`: the score (agent's estimate of final reward) for the current game state `sob`.
- `trainAgent(sob, ...)`: train agent for one episode⁶ starting from state `sob`.

⁶An *episode* is one specific game payout.

Table 1: Agents available in GBG.

agent	game	remark
generic agents		
RandomAgent	all	acts completely random
HumanPlayer	all	human play
MaxNAgent	all	generalized 'Minimax' [Korf, 1991]
ExpectimaxNAgent	all	MaxN for nondeterministic games
MaxN2Wrapper	all	MaxN wrapper around inner agent
ExpectimaxWrapper	all	ExpectimaxN wrapper around inner agent
MCAgent	all	Monte Carlo
MCTSAgentT	all	Monte Carlo Tree Search [Browne et al., 2012]
MCTSExpectimaxAgt	all	MCTS extension for nondeterministic games [Kutsch, 2017]
TDAgent	all	TD(λ) agent according to Sutton and Barto [1998] with user-supplied features
TDNTuple3Agt	all	TD(λ) agent with n-tuple features [Lucas, 2008]
SarsaAgt	all	SARSA agent (state-action-reward) [Sutton and Barto, 1998] with n-tuple features [Lucas, 2008]
game-specific agents		
AlphaBetaAgent	Connect-4	perfect Connect-4 player (alpha-beta search with opening books) [Thill, 2015]
BoutonAgent	Nim	perfect Nim player (theory of Bouton [1901])
HeurPlayer	Othello	baseline Othello player, weighted piece counter
BenchPlayer	Othello	baseline Othello player, weighted piece counter
Edax2	Othello	very strong Othello player [Delorme, 2017]

Many methods, e.g. setters, getters and other common methods, have their defaults implemented in abstract class **AgentBase**. It is strongly recommended to derive a new agent class from class **AgentBase**, i. e.

```
class AgentXYZ extends AgentBase implements PlayAgent
```

3.3.1 List of Agents implemented in GBG

Classes implementing interface **PlayAgent** and derived from **AgentBase** are shown in Table 1 and listed below:

- RandomAgent: an agent acting completely randomly
- HumanPlayer: an agent waiting for user interaction
- MinimaxAgent: a simple tree search (max-tree for 1-player games, min-max-tree for 2-player games). **Deprecated**, better use **MaxNAgent** or **ExpectimaxNAgent** for

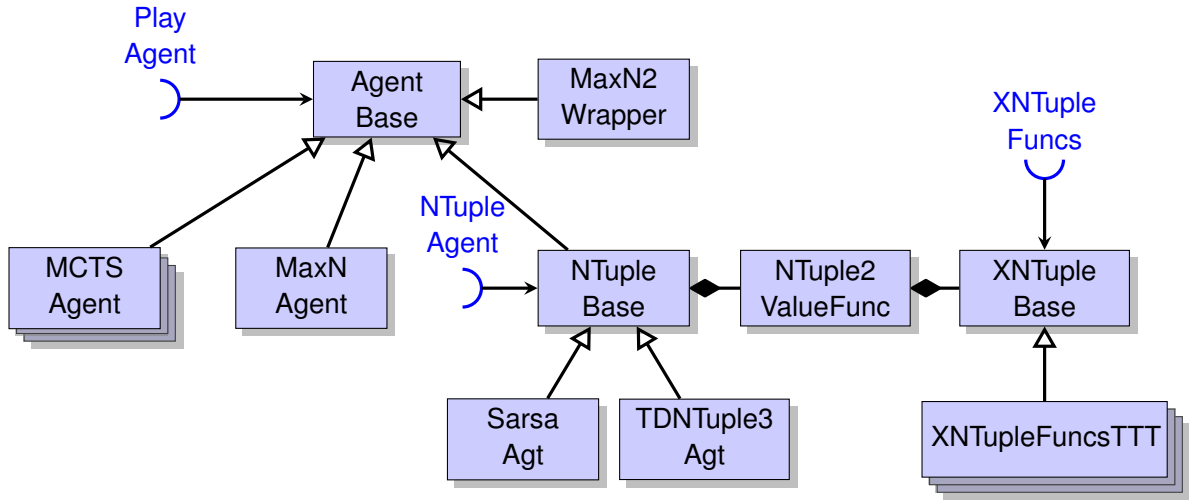

Figure 3: Class diagrams GBG: Classes around **AgentBase**.

deterministic and nondeterministic games, resp.⁷

- **MaxNAgent**: the generalization of Minimax to N-player games with arbitrary N (see [Korf \[1991\]](#)). It maximizes the k th score in a **score tuple**.
- **ExpectimaxNAgent**: the generalization of **MaxNAgent** to nondeterministic games: alternating layers of chance nodes and expectimax nodes.
- **MCAgent**: Monte-Carlo agent (no tree)
- **MCTSAgentT**: Monte-Carlo Tree Search agent
- **MCTSExpectimaxAgt**: Monte-Carlo Tree Search agent for non-deterministic games: alternating layers of chance nodes and expectimax nodes. See [Kutsch \[2017\]](#) for more details.
- **TDAgent**: general $TD(\lambda)$ agent (temporal difference reinforcement learning) with neural network value function (see Sec. 5.7 for more details). This agent requires a **Feature** object in constructor, see Sec. 3.5.
- **TDNTuple2Agt**: $TD(\lambda)$ agent with n-tuple sets. **Deprecated**, use **TDNTuple3Agt** instead.
- **TDNTuple3Agt**: $TD(\lambda)$ agent (temporal difference reinforcement learning) using n-tuple sets as features (see Sec. 5.8 and Appendix B for more details). This agent requires an object of class **XNTupleFuncs** in constructor, see Sec. 3.6.

⁷Note that Minimax is only for 2-player games, while MaxN is for 1-, 2-,..., N-player games. Note that Minimax in this simple implementation may not be appropriate for games with random elements, because Minimax follows in each tree step only *one* path of the possible successors that `advance()` may produce.

- SarsaAgt: SARSA agent (SARSA is a variant of Q-learning with state-action-pairs) using n-tuple sets as features (see Appendix B for more details). This agent requires an object of class `XNTupleFuncs` in constructor, see Sec. 3.6.

The last four agents are reinforcement learning agents (temporal difference). The last three agents (TDNTuple2Agt, TDNTuple3Agt and SarsaAgt) are based on n-tuple features. TDNTuple3Agt is the generic implementation of a TD-n-tuple-agent. More details on TD(λ) (temporal difference learning, reinforcement learning for games, eligibility traces) can be found in the technical reports Konen [2015] (outdated) and Konen and Bagheri [2020] (up-to-date, including *final adaptation*).

Each agent has an **AgentState** member, which is either RAW, INIT or TRAINED.

Some of the agents (RandomAgent, HumanAgent, `MaxNAgent`, `ExpectimaxNAgent`, MCAgent, MCTSAgent, MCTSExpectimaxAgt) are directly after construction in a TRAINED state, i.e. they are ready-to-use. They make their observations on-the-fly, starting from the given state. Other agents (TDAgent, TDNTuple2Agt, TDNTuple3Agt, SarsaAgt) require training, they are after construction in state INIT.

Classes implementing `PlayAgent` should also implement the `Serializable` interface. This is needed for loading and saving agents. Agent members which need *not* to be included in the serialization process can be flagged with keyword `transient`. Agent members which are user-defined classes should implement the `Serializable` interface as well.

3.3.2 The Wrapper Agents

There are two agents in Table 1, namely **MaxN2Wrapper** and **ExpectimaxWrapper** which can be wrapped around any other agent. This means that an inner agent is wrapped by either `MaxNAgent` or `ExpectimaxNAgent` of prescribed depth. Which of the two is taken depends on the deterministic nature of the game. If the wrapper is selected, then – instead of using the inner agent directly – a tree of prescribed depth is constructed and only at the leafs of the tree the inner agent's value function is used. This allows the agent to 'look farther' and thus make better decisions. The price to pay for this is a longer execution time. Especially if the branching factor of the game is high, wrapper depths larger than 2 or 3 should be used with caution.

The wrappers are not selectable via the agent select box in the `Arena` GUI. Instead, specify in the agent select box the inner agent, then set in tabs *Other pars* of the Params window for *Wrapper nply* a value greater than 0. Then a wrapper with depth *nply* will be constructed and wrapped around the inner agent.

As shown in Fig. 3, **MaxN2Wrapper** is not derived from `MaxNAgent` but from `Agent-Base`. This is only because it simplifies software maintenance. Algorithmically, both follow the same principles.

Figure 4: A succession of states in TicTacToe: If O makes in state **sA** the losing move leading to **sB**, then **sB** is a clear win for X, and so is the terminal state **sC**. The **game score** for **sC** from the perspective of O, the player to move in **sC**, is -1 . The **game values** (see Sec. 3.4.2) for **sB** and **sC** are $+1$ and -1 , resp.

3.4 Game Score and Game Value

3.4.1 Conventions for Game Score

Although the game score (the final result of a game, e. g. „X wins“ or „O wins with that many points“) seems to be a pretty simple and obvious concept, it becomes a bit more confusing if one wants to define the game score consistently for a broader class of states, not just for a terminal state. We use the following conventions:

- For `StateObservation so`,

```
so.getGameScore(StateObservation refer)
```

returns the sum of rewards in state `so`, seen from the perspective of the player to move in state `refer`. Most 2-player games will give the reward only in the end (win/tie/loss), so that for those games `so.getGameScore(refer)` is usually 0 as long as `so` is non-terminal. If the game state is terminal, a negative reward will be returned if `refer`'s player loses and a positive reward if this player wins. For other games there might be also rewards during the game.

- If a state is terminal (e. g. „X wins“) then the „player who moves“ has changed a last time (i. e. to player O, although the game is over.). Thus the score for O will be -1 („O loses“). It seems a bit awkward at first sight to assign a terminal state a „player to move“, but this is the only way to guarantee in a succession of actions for 2-player games that the current score estimate is always the negative of the next state's score (negamax principle). Fig. 4 shows an example.

*Example: State **sC** in Fig. 4 (TicTacToe) is a terminal state: X has made a winning move. On this terminal state O would have to move next (if it were not terminal). So the game score for this terminal state is a negative reward $\mathbf{sC.getGameScore(sC)} = -1$ for player O.*

```
sC.getGameScore(sC) = -1;
sC.getGameScore(sB) = +1;
```

```
sC.getGameScore(sA) = -1;
```

- There is the (now deprecated) method `sC.getGameScore()`, which is the game score of **sC** for the player to move in **sC**. This is deprecated, because it can be expressed equivalently as

```
sC.getGameScore() = sC.getGameScore(sC);
```

- `StateObservation.getGameWinner()` may only be called if the game is over for the current state (otherwise an assertion fires). It returns an enum `Types.WINNER` which may be one out of `{PLAYER_WINS, TIE, PLAYER_LOSES}`. The player is always the player who has to move. The method `Types.WINNER.toInt()` converts these enums to integers which correspond to $\{+1, 0, -1\}$, resp.

StateObservation defines two methods

```
public double getMinGameScore();  
public double getMaxGameScore();
```

These methods should return the minimum and maximum game score which can be achieved in a specific game. This is needed since some **PlayAgent** (e.g. `TDAgent`) make predictions of the estimated game score with the help of a neural network. Since a neural network has often a sigmoid output function which can emit only values in a certain range (e.g. $[0, 1]$), it is necessary to map the game scores to that range as well. This can only be done if the minimum and maximum game score is given.⁸

3.4.2 Difference between Game Score and Game Value

There is a subtle distinction between game score and game value. The **game score** is the score of a game state according to the game laws. For example, `TicTacToe` has the score 0 for all intermediate states, while a terminal state has either $+1/0/-1$ as game score for win/draw/loss of the player to move. In 2048, the game score is the cumulative sum of all tile merges. Each player usually wants to maximize the expectation value of 'his' score at the end of the game.

But the score in an intermediate game state is not a good indicator of the *potential* of that state. The **game value** of a state is an estimate of the final score attainable from that state. Two states in 2048 might have the same score, but the game value of these states can be different. While the first state might be close to the terminal state, the second one might have a higher mobility and thus 'last' longer and receive a higher final score. The precise game value of a state is often not known / not computable, but it is of course desirable to estimate it. An estimate can be based on a simple heuristic like the weighted piece count in chess. Or it can be based on sophisticated (deep or n-tuple) neural networks as approximators.

The main possibility to deliver a game value is:

⁸If a precise maximum game score for a certain game is not known, a reasonable 'big' estimate is usually also sufficient.

- `PlayAgent.getScore(StateObservation so)` returns the agent's estimate of the final score for the player **who has to move** in `StateObservation so` – assuming perfect play of that player. That is what we call the **game value** of `so`. The game value for 2-player games is usually +1 if it is expected that the player wins finally, 0 if it is a tie and -1 if he loses. Values in between characterize expectation values in cases where different outcomes are possible or likely (or where the agent has not yet gathered enough information or experience).

There are other methods to deliver a game value or a reward

- `StateObservation.getReward(refer, boolean)`
- `PlayAgent.estimateGameValue(StateObservation so)`

but they are only for advanced users and their description is deferred to Appendix A.

3.4.3 Ranges for Game Score and Game Value

In principle the range of game values is arbitrary, only the order of values matters for agent decisions. So a shift or stretch of the game value range should be normally irrelevant.

But there are two other reasons why the range of the game value or game score is important:

- When displaying game values on the gameboard or printing game values, it is better to have either $[-1, 1]$ or $[0, 1]$ as game value range. Classes derived from `GameBoard` will often multiply all game values by 100 and then they will display numbers in the convenient range $[-100, 100]$.
- When a neural network is used for predicting game values, it may contain a sigmoid function in the output neuron. Depending on the type of sigmoid, the range of neural network outputs is either $[-1, 1]$ or $[0, 1]$. The game values should fall into the neural network output range, otherwise the net cannot learn them.

3.5 Interface Feature

Some classes implementing `PlayAgent` need a game-specific feature vector. As an example, consider `TDAgent`, the general $TD(\lambda)$ agent (temporal difference reinforcement learning) with neural network value function. To make the neural network predict the value of a certain game state, the network needs some feature input (e.g. specific board patterns which form threats or opportunities, number of them, number of pieces and so on). These features are usually game-specific. We assume here that every feature can be expressed as double value (neural networks can only digest real numbers as input), so that the whole feature vector can be expressed as `double[]`.

To create an **Feature** object within the general `Arena`-code, the *factory method pattern* is used: `Arena` defines an abstract method

```
public Feature makeFeatureClass(int featmode);
```

The argument `featmode` allows to construct different flavors of `Feature` objects and to test and evaluate them.

In all cases where `Arena` or `ArenaTrain` needs a `Feature` object, it will call this method `makeFeatureClass(int)`. This will take place whenever a `TDAgent` object is constructed, because the `TDAgent` constructor needs a `Feature` object as parameter.

Interface `Feature` has the method

```
public double[] prepareFeatVector(StateObservation so);
```

which gets a game state and returns a double vector of features. This vector may serve as an input for a neural network or other purposes.

Implementing classes: `FeatureTTT`, `Feature2048`, ...

More details on how to set up a new `Feature` class are in Sec. 5.7.

3.6 Interface `XNTupleFuncs` and abstract class `XNTupleBase`

There are the special agents `TDNTuple3Agt` and `SarsaAgt` to realize TD- or SARSA-learning with n-tuple features. N-tuple features or n-tuple sets (Lucas [2008], Thill et al. [2014], Bagheri et al. [2015], Thill [2015]) are another way of generating a large number of features. An **n-tuple** is a set of board cells. For every game state `StateObservation` it can translate the position values present in these cells into a double score or value. In order to construct such n-tuples, the user has to implement the interface `XNTupleFuncs`. See Sec. 5.8 for more details on the member functions of `XNTupleFuncs` and Appendix B for a more detailed description of n-tuples.

To create an `XNTupleFuncs` object within the general `Arena`-code, the *factory method pattern* is used: `Arena` defines an abstract method

```
public XNTupleFuncs makeXNTupleFuncs();
```

Whenever `Arena` or `ArenaTrain` needs a `XNTupleFuncs` object, it will call this method `makeXNTupleFuncs()`. This will take place whenever an n-tuple agent object is constructed, because these n-tuple agent constructors need an `XNTupleFuncs` object as parameter.

It is strongly recommended to derive a new `XNTuple` class from class `XNTupleBase` i. e.

```
class XNTupleXYZ extends XNTupleBase implements XNTupleFuncs.
```

`XNTupleBase` is an abstract class which has however default implementations for members `instantiateAfterLoading()` and `makeBoardVectorEachCellDifferent()` and others.

Note: If you do not plan to use an n-tuple agent in your game, you do not need to implement a specific version of class `XNTupleFuncs` either. Since you do not construct an object of class `TDNTuple3Agt` or similar, `makeXNTupleFuncs()` should never be called. If it is called nevertheless, the default implementation of `makeXNTupleFuncs()` in `Arena` will throw a `RuntimeException`.

More details on how to set up a new `XNTupleFuncs` class are in Sec. 5.8.

3.7 Interface GameBoard

Interface **GameBoard** prescribes things specific to the game board. All implementing classes **GameBoardXyz** have an optional member **GameBoardXyzGui** that realizes game board GUI (usually in a separate **JFrame**). It provides functionality for:

- Maintaining its own **StateObservation** object `m_so`. This object is after construction in a default start state (e. g. empty board). The same state can be reached via `clearBoard()` or `getDefaultStartState()` as well. The associated GUI will show the default start state.
- Showing or updating the current game state (**StateObservation**) in the GUI and enabling / disabling the GUI elements (`updateBoard(...)`).
- Human interaction with the board: see Sec. 3.11.
- Returning its current **StateObservation** object (`getStateObs()`).
- `chooseStartState()`: This method returns randomly one out of a set of different start states. This is useful when training an agent in such a way that not always the same game episode is played but some variation (exploration) occurs.

*Example TicTacToe: The implementation in **GameBoardTTT** returns with probability 0.5 the default start state (empty board) and with probability 0.5 one of the possible next actions (an 'X' in any of the nine board positions).*

Classes implementing **GameBoard** should *not* inherit from **JFrame** in order to make GBG runnable also on systems without GUI capabilities. Instead, each class implementing **GameBoard** has an element **GameBoardXyzGui** `m_gameGUI` which holds all GUI-related stuff. But `m_gameGUI` can be also `null` in the non-GUI case. Example classes implementing **GameBoard** are: **GameBoardTTT**, **GameBoard2048**, ...

3.8 Abstract Class Evaluator

Class **Evaluator** evaluates the performance of a **PlayAgent**. Evaluators are called in menu item *Quick Evaluation*, during training and at the end of each *Compete* variant in menu *Competition*. It is important to note that Evaluator calls have no influence on the training process, they just measure the (intermediate or final) strength of a **PlayAgent**.

In the constructor

```
public Evaluator(PlayAgent e_PlayAgent, int mode,
                int stopEval, int verbose);
```

the argument `mode` allows derived classes to create different types of evaluators. These may test different abilities of **PlayAgent**.⁹

A normal evaluation is started by calling **Evaluator**'s method `eval` which calls in turn the abstract method

⁹For complex games it is often very difficult or impossible to have a perfect evaluator. Remember that (a) that the game tree can be too complex to know what the perfect action for a certain state is and that (b) a

```
abstract protected boolean evalAgent();
```

and counts the consecutive successful returns from that method. The argument `stopEval` sets the number of consecutive evaluations that the abstract method `evalAgent()` has to return with `true` until the evaluator is said to reach its *goal* (method `goalReached()` returns `true`). This is used in `XArenaFunc`'s method `train()` as a possible condition to stop training prematurely. This test for a premature training stop is however only done if `stopTest>0` and `stopEval>0`.¹⁰

Method `evalAgent()` needs to be overridden by classes derived from **Evaluator**. It returns `true` or `false` depending on a user-defined success criterion. In addition, it lets method `double getLastResult()` return a double characterizing the evaluation result (e.g. the average success rate of games played against MaxN player).

Concrete objects of class **Evaluator** are usually constructed by the factory method

```
abstract public Evaluator makeEvaluator(PlayAgent e_PlayAgent,
                                       int stopEval, int mode, int verbose);
```

in **Arena** or **ArenaTrain**.

Example classes derived from **Evaluator**: **EvaluatorTTT**, **Evaluator2048**, ...

More details on how to set up a new evaluator are in Sec. 5.9.

3.9 Abstract Class Arena

Class **Arena** is an abstract class for loading agents and playing games. Why is it an abstract class? – **Arena** has to create an object implementing interface **GameBoard**, and this object will be game-specific, e.g. a **GameBoardTTT** object. To create such an object within the general **Arena**-code, the *factory method pattern* is used: **Arena** defines the abstract methods

```
abstract public GameBoard makeGameBoard();
abstract public Evaluator makeEvaluator(...);
```

The first method is a factory method for **GameBoard** objects. The second method is a factory method for **Evaluator** objects. Both will be implemented by classes derived from **Arena**. That is, a derived class **ArenaTTT** can be very thin, it just implements the methods `makeGameBoard()` and `makeEvaluator()` and lets them return (in the example of Tic-Tac-Toe) **GameBoardTTT** and **EvaluatorTTT** objects, resp.

Class **Arena** has in addition the factory method

```
public Feature makeFeatureClass(int);
```

perfect **Evaluator** should evaluate the actions of **PlayAgent** for every possible state, which would take too long (or is impossible) for games with larger state space complexity. A partial way out is to have different **Evaluator** modes which evaluate the agent from different perspectives.

¹⁰`stopTest` and `stopEval` are members of **ParOther**.

If it is not overridden by derived classes, it will throw a `RuntimeException` (no game-tailored object implementing the `Feature` interface is available). If a class derived from `Arena` wants to use a trainable agent requiring `Feature` (e. g. `TDAgent`) then it has to override `makeFeatureClass`.

Class `Arena` has similarly the factory method

```
public XNTupleFuncs makeXNTupleFuncs();
```

which can be used to generate a game-tailored `XNTupleFuncs` object, if needed (if agents `TDNTuple3Agt` or `SarsaAgt` are used). If not overridden, it will throw a `RuntimeException`.

Class `Arena` has the following functionality:

- choice of agents for each player (load or set),
- specifying parameters for agents (except parameters for training),
- playing games (AI agents & humans),
- evaluating agents, competitions (one or multiple times),
- inspecting the move choices of an agent,
- logging of played games (option for later replay or analysis),
- a slider during agent-agent game play to control the playing velocity,
- tournaments (round-robin, ..., Elo, Glicko, ...).
- See Sec. 6 `Open Issues` for planned extensions to the `Arena` functionality.

Class `Arena` has in method `run()` a long switch statement on member `Task taskState` which takes one of the possible `Task` values (`PARAM`, `TRAIN`, `COMPETE`, ...) and controls what `Arena` is actually doing.

Derived abstract class: `ArenaTrain`.

Examples of non-abstract classes derived from `Arena`: `ArenaTTT`, `Arena2048`, ...
They usually have a method

```
public static void main(String[] args)
```

for starting a specific game.

3.10 Abstract Class `ArenaTrain`

Class `ArenaTrain` is an abstract class derived from `Arena` which has this *additional* functionality:

- specifying all parameters for agents (including parameters for training),
- training agents (one or multiple times),

Table 2: The Param classes in GBG.

Par...	...Params	related agents
ParTD	TDParams	TDAgent, TDNTuple3Agt, SarsaAgt (TD settings)
ParNT	NTParams	TDNTuple3Agt, SarsaAgt (n-tuple [Lucas, 2008] & temporal coherence [Beal and Smith, 1999] settings)
ParMaxN	MaxNParams	MaxNAgent [Korf, 1991], ExpectimaxNAgent and wrappers (Sec. 3.3.2)
ParMC	MCPParams	MCAgent
ParMCTS	MCTSPParams	MCTSAgentT
ParMCTSE	MCTSEParams	MCTSEExpectimaxAgent
ParOther	OtherParams	Other parameters (all agents)

- saving agents.
- See Sec. 6 Open Issues for planned extensions to the ArenaTrain functionality.

Examples of non-abstract classes derived from Arena: **ArenaTrainTTT**, **ArenaTrain2048**,

...

They usually have a method

```
public static void main(String[] args)
```

for starting a specific game.

3.11 Human interaction with the board and with Arena

During game play: How is the integration between user actions (human moves) and AI agent actions implemented?

If **GameBoard** request an action from **Arena**, then its method `isActionReq()` returns `true`. This causes the selected AI to perform a move. If on the other hand a human interaction is requested, **Arena** issues a `setActionReq(false)` and this causes `isActionReq()` to return `false` as well. **GameBoard** then waits for GUI events until a user (human) action is recorded. **GameBoard** is responsible for checking whether the human action is legal (`isLegalAction()`).¹¹ If so, then **GameBoard** issues an `advance()`. Method `advance()` opens the possibility for invoking random elements from the game environment (e. g. adding a new tile in 2048), if necessary.

When all this has happened, **GameBoard** sets its internal state such that `isActionReq()` returns `true` again. Thus it asks **Arena** for the next action and the cycle continues. Finally, **Arena** detects an `isGameOver()`-condition and finishes the game play.

¹¹ see method `HGameMove(x, y)` in `GameBoardTTT` for an example.

3.12 The Param Classes

Each agent or group of agents has associated classes for setting its parameters. Table 2 gives an overview of these param classes. These classes come in two flavours:

...Params For example, class **TDParams** holds the parameters for all parameters related to TD (Temporal Difference learning). It holds additionally the GUI (param tab) to set them. Similar for all other ...Params classes. These classes are usually derived from `Frame` or `JFrame` and as such their objects tend to be rather big.

Par... For example, class **ParTD** holds solely the parameters related to TD. Thus, objects of class `Par...` are much smaller and can be easily copied, attached to other objects, passed to other methods, saved and loaded.

It is advisable to use the classes ...Params only once for the multi-pane Param Tabs window. For all other use cases (inside agents, loading and saving to disk, ...) you should use the `Par...` variant.

Classes **ParOther** and **OtherParams** hold parameters relevant for all agents in one way or the other. Among these parameters are:

- the evaluator modes to use during quick evaluation (*Quick Eval Mode*) or during training (*Train Eval Mode*),
- parameters relevant for *all* trainable agents (`numEval`, *Episode Length*, *Choose Start 01*, *Learn from RM*),
- the option *Wrapper nPly* to wrap all agents in a n-ply look-ahead tree search (Max-N or Expectimax-N, depending on whether the game is deterministic or not).

See *GBG Help* for more detailed information.

3.13 The ACTION Classes

There are three classes (public subclasses of class `Types`) for specifying actions:

ACTIONS is an action specified by an `int` and a Boolean predicate `randomSelect` whether it was selected by a random move or not.

ACTIONS_ST is derived from **ACTIONS** and has additionally the **ScoreTuple** of this action.

ACTIONS_VT is derived from **ACTIONS** and has additionally a value table for all available actions, the value of this action and the **ScoreTuple** of this action.

3.14 GBG Starter Classes

3.14.1 GBGLaunch

GBGLaunch is the class that allows to launch all the games implemented in GBG. This can be done either via GUI or via command line arguments. See *GBG Help*, Sec. *GBG Launcher*, for details.

If a game is scalable, i.e. it comes in different variants, the scalable parameters may be specified in the launcher GUI prior to calling the game.

3.14.2 GBGBatch

GBGBatch is the class that allows to run (time-consuming) tasks in batch mode, usually without any GUI. **GBGBatch** is completely configurable via command line arguments. See *See GBG Help, Sec. GBG Batch*, for more details.

4 Design Principles

The development of GBG is based on a few design principles that should help to write well-maintainable, versatile and error-free code:

4.1 Separate GUI from core GBG

Have a clean separation of GUI elements and core GBG functionality. It should be possible to perform time-consuming GBG tasks on different machines, but not all machines are capable of executing GUI code (X11, Swing etc.). Therefore, the core GBG functionality should be runnable without any GUI elements. GBG classes should **not inherit** from GUI classes (like JFrame, JPanel). Instead, GUI elements, where necessary, should be optional members of GBG classes. 'Optional' means that these members may be `null` without obstructing any GBG core functionality. Examples:

- Class **Arena** has the optional member **ArenaGui**. **ArenaGui** extends JFrame.
- Class **ParMC** has the optional member **MCPParams**. **MCPParams** extends Frame.

When a batch program like **GBGBatch** is run, it should not need any GUI elements. Then all these optional parameters are left at their initial value `null` and the program runs even on machines without X11.

4.2 Number the Players with 0, 1, 2, ...

Players should be numbered with 0, 1, 2, ... Do not use the numbering 1, 2, 3, ..., because this needs transformations in all cases where we have arrays over players.¹² The code is less well-maintainable, since we might be unclear in which player-numbering scheme we are.

As a convention, always player 0 will start a game episode.

¹²For 2-player games there is also the string constant `String[] GUI_2PLAYER_NAME = {"X", "O"}`, but this is only for display purposes in the GUI.

4.3 Copy Constructor for **StateObservation**

All classes `StateObserverXYZ` implementing **StateObservation** should have a copy constructor and a method `copy()`. This is to ensure that really all elements of the derived class are copied.

Each class derived from **StateObservation** should usually extend **ObserverBase**.

Then the first line of the copy constructor should be `super(other);` in order to guarantee that all elements of **ObserverBase** are copied.

```
newState = new StateObserverXYZ(this); and  
newState = this.copy();
```

do the same. The latter is just a shorthand for the former.

If elements of `StateObserverXYZ` are complex objects (lists or arrays) do not forget to use the appropriate `clone()`-operations.

It is usually a bit faster (much faster in the case of Othello!) to use in the copy constructor `other.availableActions.clone()` instead of `setAvailableActions()`. Note that the clone operation makes a copy of the `ArrayList`

```
ArrayList<ACTIONS> availableActions,
```

but not of the actions contained in it. This is usually OK, since a state will not change the actions contained in `availableActions`.

4.4 Avoid Excess Copying

Think whether copying of elements is really required.

It may slow down operation. And it may be a cause of errors, if it is somehow forgotten in a part of the code to copy elements, but another part of the code silently assumes that it has been copied.

Of course there are circumstances where copying is a must, but use it only if necessary.

5 Use Cases and FAQs

5.1 My first GBG project

Follow the install and configuration tips from the GitHub Wiki:

<https://github.com/WolfgangKonen/GBG/wiki> – Install and Configure
in order to install the GBG framework.

Run **GBGLaunch** as Java Application. Once started, you can use all functionality of **Arena** and **ArenaTrain** (e. g. play, inspect, compete, train, see Sec. 3.9 and 3.10) for all games registered in **GBGLaunch**. For more detailed information on how to train an agent see Sec. 5.3.

5.2 I have implemented game XYZ and want to use AI agents from GBG – what do I have to do?

As a game developer you have to implement the following five interfaces for your game:

- StateObserverXYZ implements StateObservation
- GameBoardXYZ implements GameBoard
- EvaluatorXYZ extends Evaluator
- FeatureXYZ implements Feature, Serializable (only needed, if you want to use the trainable agent **TDAgent**, see Sec. 5.7).
- XNTupleXYZ extends XNTupleBase implements XNTupleFuncs, Serializable (only needed, if you want to use the trainable n-tuple agent **TDNTuple3Agt** or **SarsaAgt**, see Sec. 5.8).

Once this is done, you only need to write a very 'thin' class ArenaTrainXYZ with suitable constructor

```
public ArenaTrainXYZ(String title, boolean withUI)
```

Class ArenaTrainXYZ overwrites the abstract methods of class **ArenaTrain** with the factory pattern methods

```
public GameBoard makeGameBoard() {
    gb = new GameBoardXYZ(this);
    return gb;
}
public Evaluator makeEvaluator(PlayAgent pa, GameBoard gb,
    int stopEval, int mode, int verbose) {
    return new EvaluatorXYZ(pa,gb,stopEval,mode,verbose);
}
```

If needed, you should overwrite the methods (see Sec. 5.7 and Sec. 5.8)

```
public Feature makeFeaturClass(int featmode) {
    return new FeatureXYZ(featmode);
}
public XNTupleFuncs makeXNTupleFuncs() {
    return new XNTupleXYZ();
}
```

as well.

If you do not want to use the agents **TDAgent** and **TDNTuple3Agt** needing these factory methods, you may just implement stubs throwing suitable exceptions:

```

public Feature makeFeaturClass(int featmode) {
    throw new RuntimeException("Feature not implemented for XYZ");
}
public XNTupleFuncs makeXNTupleFuncs() {
    throw new RuntimeException("XNTupleFuncs not implemented for XYZ");
}

```

You can inspect class **ArenaTrainTTT** in order to see for all this an example specific to the game TicTacToe.

Finally you need to register your new game in **GBGLaunch** (optionally also in **GBGBatch**)¹³ to be able to launch your game. To do so, add a few lines of code in the switch statements of **GBGLaunch**'s methods `startGBGamePlay` and `startGBGameTrain`, similar to the statements for the other games.¹⁴

Then your game will show up the next time you start **GBGLaunch** and you can use for your game all the functionality laid down in **Arena** and **ArenaTrain** and all the wisdom of the AI agents implementing **PlayAgent**. Cool, isn't it?

5.3 How to train an agent and save it

1. Create and launch an **ArenaTrain** object
2. Select a trainable agent and set its parameters
3. Set general training-specific parameters:
 - `maxTrainNum`: *Train games* = number of training episodes (main GBG window, **ArenaTrain**),
 - `numEval`: after how many episodes an intermediate evaluation is done (*Other pars* tab),
 - `epiLength`: *Episode length* = maximum allowed number of moves in a training episode.¹⁵ (*Other pars* tab).
4. Train the agent & visualize intermediate evaluations.
5. Optional: *Inspect V* = inspect the value or *Q*-function of an agent (how it responds to certain board situations).
6. Save the agent via menu item *Agent N – Save Agent N*.

¹³This needs only one line of code in the switch statement of **GBGBatch**'s `main`.

¹⁴If your game has scalable parameters, you may want to add also appropriate code in the switch statements of **GBGLaunch**'s methods `setDefaultScaPars` and `adjustScaParGuiPart`.

¹⁵If `epiLength` is reached, the game is stopped and `PlayAgent.estimateGameValue()` is returned (either up-to-now-reward or estimate of current + future rewards). If the game terminates earlier, the final game score is returned. Set to `-1`, if no premature stop is allowed.

Note that also agents like **MCAgentN**, **MCTSAgentT** and so on are 'trainable'. That is, if *Train* or *MultiTrain* is executed on them, they will perform the desired number of self-play episodes. Of course these agents do not really 'train' i. e. modify their behavior. It is just for the side effects: (i) the number of moves per second – train time, excluding evaluation time – is measured and reported and (ii) the agents are repeatedly evaluated.

5.4 Which AI's are currently implemented for GBG?

See Sec. 3.3.1 and Table 1 for a list of all AI's (agents), i. e. classes that implement interface **PlayAgent**.

5.5 How to write a new agent (for all games)

Of course your new agent `NewAgent` has to implement the interface **PlayAgent**. It is strongly recommended that you derive your new agent from **AgentBase** to inherit basic functions with their default implementations. These functions can be overridden if necessary.

The new agent should as well implement the interface `Serializable (java.io)` to be loadable and savable. – If the agent needs instantiation after loading or parameter tabs setting after loading, add this functionality in member methods `instantiateAfterLoading` and `fillParamTabsAfterLoading()` (see Sec. 5.12). If nothing is needed here, **AgentBase** will provide appropriate (empty) dummy stubs for these methods.

There are a few places in the code where the new agent has to be registered:

- `Types.GUI_AGENT_LIST`: Add a suitable agent nickname "nick". This is how the agent will appear in the agent choice boxes.
- `XArenaFuncs.constructAgent()`: Add a suitable clause
`if (sAgent.equals("nick")) ...`
- `XArenaFuncs.fetchtAgent()`: Add a suitable clause
`if (sAgent.equals("nick")) ...`
- `XArenaTabs.showParamTabs()`: Add a suitable clause
`if (selectedAgent.equals("nick")) ...`

If the agent has new sensible default parameters, they may be added to function `setParamDefaults` in classes `TDParams`, `NTPParams` or other **Param** classes.

If the agent requires a whole set of new parameters which do not fit into the existing **Param** classes, then construct new **Param** classes `...Params` and `Par...` and add `...Params` to the **Param** tab.

5.6 What is the difference between **TDAgent**, **TDNTuple2Agt** and **TDNTuple3Agt**?

All three agents are trained by TD (temporal difference learning). They differ only in their feature vectors: While for **TDAgent** the user has to specify all features (see Sec. 3.5 through method

```
public double[] prepareFeatVector(StateObservation so),
```

the classes **TDNTuple2Agt** and **TDNTuple3Agt** construct their features automatically from the given n-tuple sets and **position values** (see Sec. 5.8 and Appendix B.1).

It is advisable to use only **TDNTuple3Agt**, because **TDNTuple2Agt** is the older TD-n-tuple variant which is likely to become deprecated in the near future (It is only temporarily here for comparison checks. It is unnecessarily complicated in source code and not generalizable to N -player games with $N > 2$).

5.7 How to apply TDAgent to a new game

Suppose you have implemented a new game XYZ and want to write a TD agent (temporal difference agent) which learns this game. What do you have to do? – Luckily, you can re-use most of the functionality laid down in class **TDAgent** (see Sec. 3.3). But a few things remain to be done:

1. Write a new class derived from **Feature**

```
public class FeatureXYZ implements Feature, Serializable
```

This is the only point where some code needs to be written: Think about what features are useful for your game. In the simplest case this might be the raw board positions, but these features may characterize the win- or the lose-probability for a state only rather indirectly. Other patterns may characterize the value (or the danger) of a state more directly. For example, in the game TicTacToe any two-in-a-line opponent pieces accompanied by a third empty position pose an immanent threat. A typical feature may be the count of those threats. Another way to form features is to count the number of pieces for each player and let a network learn weights for it. Or the number of pieces in certain positions on the board.¹⁶

2. Add to ArenaXYZ and ArenaTrainXYZ the overriding method

```
public Feature makeFeatureClass(int featmode) {
    return new FeatureXYZ(featmode);
}
```

TDAgent will generate by reinforcement learning a mapping from feature vectors to game values (estimates of the final score, see Sec. 3.4.2) for all relevant game states.

The class ArenaTrainTTT (together with FeatureTTT) may be inspected to view a specific example for the game TicTacToe.

¹⁶The drawback of all these features is that they are not very generic: The user has to code the features in a game-dependent way for each new game again. – N-tuple sets (Lucas [2008], Thill et al. [2014], Bagheri et al. [2015], Thill [2015]) are another way of generating a large number of features in a generic way (but they are not part of **TDAgent**, see Sec. 5.8, Appendix B and **TDNTuple3Agt** instead).

5.8 How to apply TDNTuple3Agt agent to a new game

Suppose you have implemented a new game XYZ and want to write a TD (temporal difference) agent using n-tuples which learns this game. What do you have to do? – Luckily, you can re-use most of the functionality laid down in class **TDNTuple3Agt** (see Sec. 3.3). But a few things remain to be done:

1. Write a new class that implements **XNTupleFuncs** (Sec. 3.6) and is derived from **XNTupleBase**

```
public class XNTupleFuncsXYZ extends XNTupleBase
    implements XNTupleFuncs, Serializable
```

Here you have to code some rather simple things like `getNumCells()`, the number of board cells in your game, and `getNumPositionValues()`, the number of **position values** that can appear in each cell. This is for example 9 and 3 (O/empty/X) in the game TicTacToe.

Next you implement the **BoardVector**-creating method

```
BoardVector getBoardVector(so)
```

which transforms a game state `so` into a board vector (length: `getNumCells()`). See Appendix B.1 for board cell numbering and a specific example.

If your game has **symmetries** (the game TicTacToe has for example eight symmetries, 4 rotations \times 2 mirror reflections), you implement the method

```
BoardVector[] symmetryVectors(BoardVector boardVector, int n)
```

which returns in case '`n=0` or `n=s`' for a given board vector all symmetric board vectors (including itself). If the game has no symmetries, it returns just the board vector itself. If $0 < n < s$, this method returns the board vector itself plus $n-1$ (randomly selected) of the s symmetry vectors. (This n -option is for games where the full set of symmetry vectors is too big (e.g. Sim and Nim). n is set via element *nSym* in the *NT pars* (n-tuple params) tab.)

There is also a sibling method

```
BoardVector[] symmetryVectors(StateObsWithBoardVector, int n)
```

which is for games where the symmetric states can only be constructed if access to the underlying **StateObservation** object is provided. This is for example the case in the games Sim and Rubik's Cube. For other games where this is *not* necessary, you just implement *nothing*. Then the default implementation from **XNTupleBase** is taken:

```
XNTupleBase.symmetryVectors(StateObsWithBoardVector, int n)
```

which just calls `symmetryVectors(BoardVector, int n)`.

The method

```
HashSet adjacencySet(int iCell)
```

returns the set of cells adjacent to the cell with number `iCell`. Whether adjacency is a 4-point- or an 8-point-neighborhood or something else is defined by the user. This function is used by **TDNTuple3Agt** when creating the shape of new n-tuples by random walk.

Finally you implement

```
int[][] fixedNTuples()
```

a function returning a fixed set of n-tuples suitable for your game. If you do not need fixed n-tuple sets, you may leave `fixedNTuples()` unimplemented (i. e. let it throw an exception) and select in the *NT pars* (n-tuple params) tab the check box *Random n-tuple generation*.

2. Add to ArenaXYZ and ArenaTrainXYZ the overriding method

```
public XNTupleFuncs makeXNTupleFuncs() {  
    return new XNTupleFuncsXYZ();  
}
```

The class `ArenaTrainTTT` (together with `XNTupleFuncsTTT`) may be used as a template, showing the implementation for the game `TicTacToe`.

TDNTuple3Agt offers several possibilities to construct n-tuples:

- (a) using a predefined, game-specific set of n-tuples (see `fixedNTuples()` above),
- (b) random n-tuples generated by random-cell-picking (the cells in an n-tuple are in general not adjacent), and
- (c) random n-tuples generated by random walk (every cell in each n-tuple is adjacent to at least one other cell of this n-tuple; needs method `adjacencySet`, see above).

A cell may (and often should) be part of several n-tuples.

The same remarks apply if you want to specialize **SarsaAgt** or **TDNTuple2Agt** (now deprecated) to a new game.

See Appendix B for further information on n-tuples.

5.9 How to set up a new **Evaluator**

Setting up a good evaluator for a game is not an easy task, because the agent's strength in playing a game depends on its reaction to *all* possible game states, weighted with the relevance of those states. To evaluate this is for most realistic games an intractable task. It can often be only approximated by having different evaluators looking at the problem from different perspectives. Therefore, the **Evaluator** concept in GBG allows for different evaluator modes.

When testing a deterministic agent against another deterministic opponent, they will always play the same episode, so that the evaluation covers only a tiny part of the complete game tree. And there are only three possible outcomes: win, tie or loss, i.e. $\{+1, 0, -1\}$. As a consequence it is difficult to decide whether an agent improves or not. A little improvement is achieved when the start state is varied (randomly or by looping through a prescribed set of states). Then the visited fraction of the game tree is slightly bigger. More importantly, the evaluation result is a floating point number (win rate, averaged over a set of different episodes), which signals better than $\{+1, 0, -1\}$ whether an agent improves or not. Therefore, most classes derived from **Evaluator** should have modes with different start states.

These general aspects should be kept in mind when constructing for a game a new evaluator derived from **Evaluator**. It is often a good idea to specify different modes where the agent plays against different opponents, either from the default start state or from a set of start states.

When deriving a concrete class from **Evaluator**, you have to implement the abstract methods of class **Evaluator**, the most important ones are:

- `getAvailabelModes()`: returns an `int[]` with all available modes,
- `evalAgent()`: run the evaluator with the mode specified in constructor,
- `getTooltipString()`: return a `String` (may be multi-line) describing the different modes (tooltip text of the evaluator mode choice boxes in `OtherParams`).

A typical constructor `EvaluatorXYZ` extends **Evaluator** looks like:

```
public EvaluatorXYZ(PlayAgent e_PlayAgent, GameBoard gb, int stopEval,
                   int mode, int verbose) {
    super(e_PlayAgent, mode, stopEval, verbose);
    ...
}
```

5.10 Scalable GUI fonts

When writing a new GUI element, this GUI element may be shown on display screens with largely differing screen sizes. In order to have legible fonts on all such screen sizes, it is advisable NOT to use explicit font sizes like 12, 14, Instead it is better to use variable font sizes

```
int Types.GUI_HELPFONTSIZE
int Types.GUI_DIALOGFONTSIZE
```

and similar (see `Types.java`). To define a new font, use for example the form

```
Font font=new Font("Arial",0,(int)(1.2*Types.GUI_HELPFONTSIZE));
```

where the factor 1.2 is optional, if you want to adjust the appearance of the associated text element.

The variable font sizes are automatically scaled to be a certain portion of the screen width. If you want **all** fonts to appear bigger or smaller, you may set

```
double Types.GUI_SCALING_FACTOR
```

in `Types.java` to a value slightly higher or lower than 1.0.

5.11 What is a ScoreTuple?

A **ScoreTuple** has a vector

```
public double[] scTup
```

of size N containing the **game score** or **game value** – depending on context – for each player $0, 1, \dots, N - 1$.

The class has methods to combine the current **ScoreTuple** `this` with a second **ScoreTuple** `tuple2nd` according to one of the following operators:

AVG weighted average or expectation value: add `tuple2nd`, weighted with a certain probability weight. The probability weights of all combined tuples should sum up to 1.

MIN combine by retaining this **ScoreTuple**, which has in `scTup[playNum]` the lower value.

MAX combine by retaining this **ScoreTuple**, which has in `scTup[playNum]` the higher value.

DIFF subtract from `this` all values in the other `tuple2nd`.

5.12 What is the purpose of **PlayAgent**'s `instantiateAfterLoading()` and `fillParamTabsAfterLoading()`?

When saving an agent to disk, some agents may not save all their members. Reasons for this are: (a) the member may not be serializable, (b) the member would make the saved agent too big and is not needed for reconstructing it. If the agent is re-loaded from disk, these members will be 0 or null. To fully instantiate the agent, we need the method `instantiateAfterLoading()`. This will for example allocate memory for an array, read in static opening books or do other things. Having this method as part of **PlayAgent**'s interface makes the code simpler in all cases where we need this instantiation.¹⁷

¹⁷Before, a lengthy `switch`-statement with many cases and agent-dependent casts was needed.

Similarly, most agents will have parameters which are restored from disk. To make these parameters visible, the appropriate param tabs need to be filled with their values. Method `fillParamTabsAfterLoading()` has the appropriate code for this.

If an agent needs nothing to be done in one or both cases, the implementer of the agent has nothing to do as well: The base class `AgentBase` – from which the agent should be derived – has dummy stubs for both methods: they just do nothing.

6 Open Issues

The current GBG class framework is still under development. The design of the classes and interfaces may need further reshaping when more games or agents are added to the framework. There are a number of items not fully tested or not yet addressed:

- Undo/redo possibilities
- Game balancing
- Client-server architecture for game play via applet on a game page. Option for a 'hall of fame'. An example for the game Sim is available from TU Wien ¹⁸.
- Replay memory for better training: This idea has been used by DeepMind in learning Atari video games. Played episodes are stored in a replay memory pool and used repeatedly for training.
- The extension of TD-agents to N -player games with $N > 2$ is fully functional but so far tested only on 3-player Sim in a near-trivial configuration (results nearly always in a tie). It is desirable to test it on non-trivial 3-player games. One option may be a 3-player Sim with pre-defined coalition (similar to Skat) or the game Skat itself.

¹⁸<http://www.dbai.tuwien.ac.at/proj/ramsey>

A Appendix: Other Game Value Functions

Sec. 3.4 and 3.4.2 have introduced with

```
StateObservation.getGameScore(refer)
PlayAgent.getScore(StateObservation sob)
```

the main functions to retrieve a **game score** or **game value**, resp. There are two other functions delivering a game value; they are only required for more advanced needs:

- Interface **StateObservation** delivers with

```
getReward(StateObservation refer, boolean rgs)
```

a function returning the **game reward**. This reward is simply the same as game score in case `rgs==true` ('reward is **game score**'), but it can be also another (game-specific) function in case `rgs==false`. This opens the possibility that the reward might be something different from game score. Example: In the game 2048, a possible reward for a state can be the number of empty tiles in that state.

- Interface **PlayAgent** delivers with `estimateGameValue(so)` a function (perhaps trainable / adjustable from previous experiences) that estimates the future game value at end of play. The difference to `PlayAgent.getScore(StateObservation so)`: `estimateGameValue(so)` may NOT call `getScore(so)` or `getNextAction(so)`, since these functions may call `estimateGameValue(so)` inside (e.g. if a certain episode length is reached) and this would result in infinite recursion. A simple implementation can be to return just `so.getReward(rgs)`, but other implementations are possible as well.

A potential use of `pa.estimateGameValue(sob)` is to compute in MC or MCTS the final value of a random rollout in cases where the rollout did not reach a terminal game state (since the episode lasts longer than the 'Rollout depth' as it is for example in 2048 often the case).

A second use of `pa.estimateGameValue(sob)` is in trainable agents, when the maximum training episode length (if any) is reached.

A third use of `pa.estimateGameValue(sob)` is in **MaxNAgent** when the tree depth is reached but the game is not yet over. Then we call `pa.estimateGameValueTuple(sob)`.

A fourth use of `pa.estimateGameValue(sob)` is in wrapper **MaxN2Wrapper** and **ExpectimaxWrapper** (Sec. 3.3.2) when the prescribed n-ply tree depth is reached. These wrappers implement `estimateGameValue(sob)` and let it return the wrapped agent's game value via

```
wrappedAgt.getScore(sob)
```

where `sob` is the state at the leaf node of the wrapper tree.

It is dependent on the class implementing **PlayAgent** what

Table 3: Summary of all game score and game value functions in GBG.

method	remark
class StateObservation (so)	
getGameScore()	<i>(deprecated)</i> game score of <code>this</code>
getGameScore(refer)	game score of <code>this</code> relative to referring state <code>refer</code>
getGameScore(int i)	... relative to player <code>i</code>
getGameScoreTuple()	a <code>ScoreTuple</code> with game scores for all players
getReward(rgs)	<i>(deprecated)</i> the game reward of <code>this</code>
getReward(refer,rgs)	game reward of <code>this</code> relative to referring state <code>refer</code>
getReward(int i,rgs)	... relative to player <code>i</code>
getRewardTuple(rgs)	a <code>ScoreTuple</code> with rewards for all players
class PlayAgent (pa)	
getScore(so)	the game value = agent's estimate of <code>so</code> 's final score
getScoreTuple(so)	a <code>ScoreTuple</code> with game values for all players
estimateGameValue(so)	agent's estimate of game value for <code>so</code>
estimateGameValueTuple(so)	a <code>ScoreTuple</code> with agent estimates for all players

`estimateGameValue(sob)`

actually returns. If it is too complicated to train a value function (or if it is simply not needed, because for a game like TicTacToe we come always to an end during rollout), then `estimateGameValue(sob)` may simply return `sob.getReward(rgs)`.

If we integrate a trainable game value estimation into a class implementing **PlayAgent**, then agents that formerly did not need training (Minimax, MC, MCTS, ...) will require training. They should be after construction in **AgentState** INIT. How the training is actually done depends fully on the implementing agent.

Table 3 gives an overview over all functions in GBG returning a game score or a game value. Summary of main facts:

- `so.getGameScore()` is deprecated, because it can be expressed equivalently via `so.getGameScore(so)`.
- `getReward(...,rgs)` returns `getGameScore(...)`, if `rgs==true`. Otherwise it returns a specific reward, depending on the nature of the game (whatever the class derived from **StateObservation** implements).
- `getReward()` and `getGameScore()` return the *cumulative* reward and game score for the `StateObservation` object `this`. If the user wants the delta reward, he/she has to subtract the reward of the preceding state.
- `getReward(...)` is used in all places where agents reason about the next action. This is in move calculation (`getNextAction2`), in `estimateGameValue...` and during training.

- If a game has its **StateObservation** class derived from **ObserverBase** and it does not implement `getReward(...)`, then default implementations from **ObserverBase** are taken which implement the reward just as game score and issue a warning when called with `rgs==true`.
- `pa.getScore` returns the agent's estimate of the **game value**, i.e. the estimate of the final score attainable for `pa` – assuming perfect play. To calculate this, it may ask a model (e.g. NN or some weighted piece-position formula), or it may perform recursive search up to a tree depth / rollout depth, depending on the nature of the agent. If the maximum depth is reached, it may call `estimateGameValue`.
- `pa.estimateGameValue` returns also an game value estimate. But it returns a coarser estimate, since it may not call `getScore` back (to avoid an infinite loop).
- All **game score** and **game value** methods have associated `...Tuple` versions: They return instead of a single game score or game value a **ScoreTuple** (Sec. 5.11) of N values for all players $0, 1, \dots, N - 1$.

B Appendix: N-Tuples

B.1 Board Cell Numbering and Board Vectors

Each n-tuple is a list of board cells [Lucas \[2008\]](#). Board cells are specified by numbers. The canonical numbering for a rectangular board is row-by-row, from left to right. For example, a 4×4 board would carry the numbers

```
00 01 02 03
04 05 06 07
08 09 10 11
12 13 14 15
```

Other (irregular) boards may carry other (user-specified) cell numbers. Each choice of numbering is o.k., it has only to be used consistently throughout the game.

Given the board cell numbering, the method

```
BoardVector XNTupleFuncs::getBoardVector(StateObservation so)
```

returns a **board vector**: Each **BoardVector** object contains an `int[]` vector whose length is the number of board cells

```
int XNTupleFuncs::getNumCells(),
```

carrying the position value for each board cell according to this numbering.¹⁹ The **position value** of a cell is a game-specific coding of all states a board cell can be in. It is a number in $\{0, 1, 2, \dots, P - 1\}$ with $P = \text{XNTupleFuncs::getNumPositionValues}()$.

¹⁹In the game Sim, the 'board cells' are the links in the Sim graph. In the game Rubik's Cube, the 'board cells' are the cubie faces (stickers) needed to uniquely define a cube state.

Figure 5: Two examples for n-tuples: (a) 3 n-tuples, (b) 4 n-tuples of varying length and placement.

*Example: The canonical board cell numbering for the game TicTacToe run from 00 to 08. The position values are 0: O, 1: empty, 2: X. Each **BoardVector** object has length 9. For state **sA** in Fig. 4 the board vector is*

`bVec = {1, 1, 0, 1, 2, 2, 1, 1, 1};`

B.2 N-Tuple Creation

N-tuple sets can be created through explicit specification by the user (n-tuple fixed mode) or through a random initialization process.

Fig. 5 shows two examples of 4×4 boards with fixed (user-specified) n-tuple sets. The canonical cell number is obtained from

$$4 \times \text{row_number} + \text{col_number}$$

*Example (a) in Fig. 5 is coded in a class derived from **XNTupleFuncs** as*

```
public int[][] fixedNTuples() {
    int nTuple[][]={ {0,1,2,3}, {1,5,6,2}, {0,4,8,9,10,11} };
    return nTuple;
}
```

Example (b) is coded as

```

public int[][] fixedNTuples() {
    int nTuple[][]={ {4,5,6,7}, {2,6,7,3}, {0,4,8,9,13}, {10,11} };
    return nTuple;
}

```

Each n-tuple contains each cell at most once. But a set of n-tuples may (and often should) contain the same cell multiple times.

The following **random** initialization processes to create n-tuple sets are provided by the n-tuple factory:

1. **Random points:** Cells are picked at random, no cell twice²⁰, no topographical connection. This is often not advantageous because in many board games the neighborhood of a cell is more important for determining its value than an arbitrary other more distant cell.
2. **Random walks:** Cells are picked at random, no cell twice, with adjacency constraint. That is, each cell of the n-tuple list must be *adjacent* to at least one other cell in the n-tuple. What *adjacent* actually means in a certain game is specified by the user through the **XNTupleFuncs** method

```

public HashSet adjacencySet(int iCell);

```

which returns the set of all neighbors of cell iCell.

B.3 N-Tuple Training and Prediction

How are the n-tuples used to generate features? – Each n-tuple has an associated look-up table (LUT) of length P^n where n is the n-tuple length and P is the number of **position values** each cell might have.

Example: TicTacToe has $P = 3$ cell position values: $\{0, -, X\}$. For an n-tuple of length $n = 2$ this leads to $3^2 = 9$ possible LUT entries

$\{00, 0-, 0X, -0, --, -X, X0, X-, XX\}$

These LUT-entries are features. Even for a small number of n-tuples this will generate quite a large number of features. For example in Fig. 5(a), if we assume 3 **position values** for each cell, the number of features is $3^4 + 3^4 + 3^6 = 891$, because there are 2 4-tuples and one 6-tuple. On a larger board, a more realistic setting would be, for example, 40 n-tuples of length 8, resulting in $40 \cdot 3^8 = 262\,440$ features.

Each feature i in n-tuple ν has an associated weight $w_{\nu,i}$. Given a certain board state, we look first which of those features are active ($x_{\nu,i} = 1$) or inactive ($x_{\nu,i} = 0$) in that board state. Then the n-tuple network computes its estimate $V^{(est)}$ of the game value through

$$V^{(est)} = \sigma \left(\sum_{\nu=1}^m \sum_{i=0}^{P^n-1} w_{\nu,i} x_{\nu,i} \right) \quad (1)$$

²⁰within the same n-tuple

Table 4: Summary of various multi-core threads in GBG.

method	remark
class MCAgent, MCAgentN	
getNextAction_PAR	parallelization over available actions
getNextAction_MassivePAR	parallelization over available actions AND over rollouts
class EvaluatorHex	
competeAgainstMCTS_diffStates_PAR	parallelization over different start states for eval mode 10 & agent TDNTuple3Agt
class Evaluator2048	
eval_Agent	two parallelizations over evaluation games for 2 agents MCTS-Expectimax & ExpectimaxWrapper

which is a simple a neural net without hidden layer and with a sigmoid function $\sigma(\cdot)$.²¹ We compare the estimate generated by this net with the target game value V prescribed by TD-learning. A δ -rule learning step with step-size α (gradient descent) is made for each weight in order to decrease the perceived difference $\delta = V - V^{(est)}$ between both game values (Thill et al. [2014], Thill [2015]).

For complex games it might be necessary to train such a network for several hundred thousand or even million games in order to reach a good performance. The so-called **eligibility traces** are a general technique from TD-learning to speed up learning. They can be activated in the GBG framework by setting parameter $\lambda > 0$ in the *TD pars* parameter tab. Further details on eligibility traces are found in Thill et al. [2014].

Once the network is trained, the game value estimate $V^{(est)}$ is used to decide about the next action.

To further speed up learning, symmetries may be used: **Symmetries** are transformations of the board state which lead to board states with the same game value. If weights for symmetric states are trained simultaneously, this will lead to better generalization of the trained agent. For example, TicTacToe and 2048 have eight symmetries (4 rotations \times 2 mirror reflections). Instead of performing only *one* learning step with the board state itself, one can do *eight* learning steps by looping through all symmetric states. This may greatly speed up learning, since more weights can learn on each move and the network generalizes better.

If the game has symmetries, the user has to code them in **XNTupleFuncs** method

```
public BoardVector[] symmetryVectors(BoardVector boardVector, int n);
```

See Sec. 5.8 for further information on this method.

²¹In TDNTuple3Agt the sigmoid function is always $\sigma = \tanh$ (see helper class NTupleValueFunc), so that $V^{(est)} \in [-1, 1]$ holds.

C Appendix: Multi-Core Threads

GBG supports for several time-consuming operations multi-core (parallel) threads to speed up calculation. The operations are given in Table 4.

Note that an operation can only be parallelized, if the relevant routines and agents are thread-safe. This is for example the case for agent `TDNTuple3Agt` when it is evaluated (where its method `getNextAction2` is needed): This method does not change any data of this agent, so different threads can use the same `TDNTuple3Agt` object and call this method independently. This is what we do in the parallel thread of `EvaluatorHex`.

On the other hand, an agent like `MCTS` is not thread-safe, because each call to `getNextAction2(sob,...)` with a different state `sob` would construct different `MCTS` tree data. The only way to parallelize game play with `MCTS` is that each thread has its own copy of an `MCTS` with the parameters given. This is exactly what we do in the two parallel threads in `Evaluator2048`.

D Appendix: String Representations of Agents

Table 5 shows and distinguishes different methods for agent string representations.

Table 5: Summary of various agent string representation methods in GBG.

method	remark
<code>getName</code>	the name given to the constructor of the agent, e.g. <code>TD-Ntuple-3</code> (see <code>Types.GUI_AGENT_LIST</code>)
<code>getClass.getSimpleName</code>	the simple name of the underlying class, e.g. <code>TDNTuple3Agt</code>
<code>getClass.getName</code>	the full class name, e.g. <code>controllers.TD.ntuple2.TDNTuple3Agt</code>
<code>stringDescr</code>	simple class name + parameter settings
<code>stringDescr2</code>	full class name + additional parameter settings

If a class derived from `AgentBase` does not specify `stringDescr` and `stringDescr2`, then the default implementation from `AgentBase` is taken, which is only the simple and the full class name, resp.

E Appendix: Files Written by GBG

Table 6 shows and distinguishes the files written by GBG.

²²The file `theNtuple.txt` is not meant for permanent storage. It is only an intermediate print-out of a certain n-tuple configuration (perhaps a good-working one generated by random walk) and enables to copy it into the source code of a game as a fixed n-tuple mode.

Table 6: Summary of all files written by GBG.

filename	directory	remark
text files		
playStats.csv	agents/<game>[/<subdir>]/csv	statistics of a 'Play' episode
multiTrain.csv	agents/<game>[/<subdir>]/csv	multi-training results
theNtuple.txt ²²	agents	n-tuple configuration (last loading)
binary files		
*.agt.zip	agents/<game>[/<subdir>]	saved agents
*.tsr.zip	agents/<game>[/<subdir>]/TSR	tournament system results
*.gamelog	logs/<game>[/<subdir>]	log files
